- In the United States, the 2012-2013 academic year, there were a total of 20.4 million students in degree-granting institutions.
- More than 80% of them received financial aid.
- Studies have shown that financial aid is one of the most important factors in attracting student and is vital to enrollment management.

Enrollment management consisted of approaches to help university to meet the established goal such as:

- Attract more high-caliber students.
- Diversify student body.
- Increase retention.
- Improve graduation rate.

- Scholarship is the focused type of financial aid of the study.
- Scholarship is the major marketing tool for targeting students.
- Scholarship helps the university:
 - ① Giving more access to families who need help.
 - ② Stimulating more students to major in area having labor shortage.
 - ③ Diversifying the student body.
- Merit-based scholarship.

- 1 **Non-optimal** usage of scholarship budget at university:
 - Over-spending scholarship budget would reduce revenue.
 - Under-spending scholarship would potentially undermine enrollment number and revenue.
- 2 The tuition income accounts for 48% of the yearly revenue of the university under study.
- 3 The optimal allocation of scholarship problem has **not** been widely studied in literatures.

- Research questions:
 - ① How does scholarship affect student's decision?
 - ② What is the optimal scholarship for each student under the overall budget?
 - ③ What is the ideal scholarship budget for school?
- Contribution:

Utilized various data mining and optimization techniques to solve the above questions.

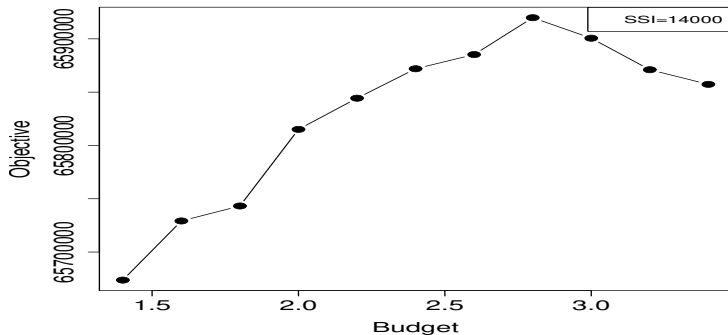

Results example

Enrollment probability of students with various background under different scholarship level.

GPA 2.9, ACT 19										
	Student	0	1000	2000	3000	4000	5000	6000	7000	8000
1	2.9-Tier1-19-White	59.55	64.63	69.39	73.77	77.73	81.24	84.31	86.96	89.22
2	2.9-Tier5-19-White	36.96	40.20	43.53	46.92	50.34	53.75	57.13	60.45	63.67
GPA 3.3, ACT 25										
3	3.3-Tier1-25-Hispanic	23.80	27.44	31.42	35.69	40.20	44.88	49.65	54.43	59.13
4	3.3-Tier1-25-White	55.60	59.32	62.94	66.42	69.72	72.84	75.75	78.43	80.90
GPA 3.8, ACT 28										
5	3.8-Tier1-28-White	42.29	46.05	49.85	53.65	57.41	61.08	64.63	68.03	71.25
6	3.8-Tier4-28-White	20.54	22.87	25.37	28.05	30.89	33.89	37.02	40.26	43.60

Results example

Using prediction of enrollment, graduation and number of years as input, and the optimization model yields:

Impact of the increasing tuition on enrollment decisions.

Questions include [Leslie and Brinkman, 1987, 1988, Heller, 1997, Ehrenber, 2004, Crouse, 2015]:

- What happens to the enrollment when universities raise their tuition?
- What is the net impact of higher tuition and reduced enrollment upon institutional finance?
- Who will not attend university because of the increasing tuition?

- The increasing tuition leads to reduction in enrollment:
 - ① Leslie and Brinkman [1987] found that every \$100 tuition increase came with a 0.7% drop in enrollment.
 - ② Crouse [2015] found a \$100 increase in tuition would lead to a decline in enrollment of about 0.88%.

Targeting effects of financial aid vs broader effects of tuition.

- 1 The following group of students are more sensitive to changes of tuition:
 - Low income students [Crouse, 2015].
 - African American and Latino students [Hossler et al., 1989].
- 2 High-caliber students are less sensitive to the increase of tuition [Heller, 1999].

Objective of the mathematic modeling in the literature:

- 1 Maximize index: SAT [Ehrenberg and Sherman, 1984, Sugrue, 2010].
- 2 Maximize tuition revenue [Thanh and Haddawy, 2007].

Constraints of the mathematic modeling in the literature:

- 1 Capacity and faculty-student ratio [Thanh and Haddawy, 2007].
- 2 Availability of students in expected SAT range, budget, and capacity [Sugrue, 2010].

Issues of these studies:

- 1 Did not address the allocation of financial aid for students with various socioeconomic characteristics.
- 2 Did not address how to optimally allocate scholarship at the aggregate level.

- The outcome of enrollment and graduation problem is binary (yes or no).
- It is a two-class classification problem.
- Common methods for two-class classification problem:
logistic regression, decision tree, svm, etc,.

Logistic Regression

Logistic regression was used as the base line model.

Why linear regression does not work?

The goal of logistic regression is to find:

- Best fitting model to describe the relationship between the binary outcome and a set of independent variables.

Logistic Regression: Variables

- 1 Academic: HS GPA, ACT/SAT, HS Percentile.
- 2 Financial: Pell Grant, EFC, Out-of-pocket, Scholarship, Unemployment rate.
- 3 Demographic: High School, Tier, Ethnicity.

Number of years prediction

- It is a regression problem.
- The following methods are compared to predict the years of stay in school:

	10-Fold Cross Validation		Test Data	
Model	RMSE	MAE	RMSE	MAE
GLM	1.40	1.2	1.53	1.26
SVM (Linear Kernel)	1.44	1.20	1.62	1.32
Decision Tree	1.43	1.24	1.43	1.23
Stochastic Gradient Boosting	1.40	1.19	1.40	1.19

- 1 The prediction of enrollment and graduation provide some insights of how students response to the various scholarship.
- 2 They have not addressed the allocation of limited scholarship budget to students fundamentally.

Sets:

- I : set of applicants, indexed by i and j
- M : different levels of scholarship awards, indexed by m
 $m \in M = \{0, 1000, 2000, \dots, 8000\}$

Variables:

- x_{im} : binary, whether a scholarship award m is allocated to applicant i or not

Parameters:

- p_{im}^e : probability of enrollment for applicant i , if given award m
- p_{im}^g : probability of graduation for applicant i , if given award m
- N_{im} : expected number of years student i stays at the institution, if given award m
- $d(i, j)$: 1 if applicant i dominates applicant j ; 0 otherwise
- B : total budget for financial aid
- A_m : monetary value of award m
- T_i : tuition paid by applicant i
- SSI_i : government compensation for applicant i graduates

Maximize the total revenue: Tuition revenue + SSI income:

$$\max \quad \sum_{i \in I} \sum_{m \in M} x_{im} \cdot p_{im}^e \cdot (T_i - A_m) \cdot N_{im} + \sum_{i \in I} \sum_{m \in M} x_{im} \cdot p_{im}^e \cdot p_{im}^g \cdot SSI_i$$

- 1 Each student only gets one scholarship:

$$\sum_{m \in M} x_{im} = 1 \quad \forall i \in I$$

- 2 Total budget constraint:

$$\sum_{i \in I} \sum_{m \in M} x_{im} \cdot p_{im}^e \cdot A_m \leq B$$

- 3 Dominance constraint:

$$\sum_{m \in M} x_{im} \cdot A_m \geq \sum_{m \in M} x_{jm} \cdot A_m \quad \forall (i, j) | d(i, j) = 1$$

Pair-wise Dominance Constraints

Around 5,500 applicants each year.

For the dominance constraints:

There are $(5,500 \times 5,500)/2$ or more than 15 million constraints.

Applicant	GPA	ACT
1	2.9	18
2	3.7	21
3	3.8	30
4	2.7	21
5	3.3	17
6	3.9	27

Full and redundant dominance

$$\sum_{m \in M} x_{im} \cdot A_m \geq \sum_{m \in M} x_{jm} \cdot A_m \quad \forall (i, j) | d(i, j) = 1$$

There are total 11 constraints in this case, 6 of them are redundant.

Minimum dominance

	1	2	3	4	5	6
1	0	0	0	0	0	0
2	1	0	0	1	1	0
3	0	1	0	0	0	0
4	0	0	0	0	0	0
5	0	0	0	0	0	0
6	0	1	0	0	0	0

Piecewise linear regression based policy

Piecewise linear regression using composite score:

Composite Score	# of Applicants	Scholarship Amount
0-53.9	2,897	0
54-68.9	2,103	$309 \times CS - 16,380$
69-76.9	241	$101 \times CS - 2,024$
77-80	19	$711 \times CS - 48,910$

Piecewise linear regression based policy

Simplified version of policy in piecewise regression form.

Composite Score	Scholarship Amount	# of Applicants
0-54.9	0	3,074
55-59.9	1,500	872
60-65.9	2,500	812
66-69.9	3,500	298
70-74.9	4,500	166
75+	6,000	38

Note: 41.6% applicants receive scholarship.

- The result of the study has been successfully implemented in the state university and has resulted in millions of financial benefits.
- The research would be applicable to many other institutions and offers a methodology, tools and insights into the solution of financial aid problems.

Wright Promise	669	346	1500	\$519,000		1072	493	1500	\$739,500	
Raider Excellence	787	366	2500	\$915,000		673	281	2500	\$702,500	
Paul Dunbar	442	190	2500	\$475,000		436	190	2500	\$475,000	
APS3500	249	88	3500	\$308,000						\$1,988
APS4500	186	71	4500	\$319,500						
APS6000	34	8	6000	\$48,000	\$2,417					
Commended	28	12	14000	\$168,000						
Val/Sal	184	119	8750	\$1,041,250		155	80	8540	\$683,200	
									\$	
		1200		\$3,793,750	\$3,161		1044		2,600,200	\$2,490

Total Merit Number Increase:
 $(1200-12-119-190)-(1044-80-190)=105$

One Year Tuition Increase:
 $105*(8750-2417)=664,965$

Four Year Revenue Increase(50% graduation rate):
 $(664,965*4 + 105*12000)*0.5 =$
\$1,959,930

Summary

- 1 A series of models are developed to predict:
 - Enrollment probability
 - Graduation probability
 - Number of years of stay
- 2 Developed minimum cardinality dominance table to reduce the model size.
- 3 An optimization model is developed with the objective to maximize the revenue.
- 4 A regression analysis is developed to translate the optimization results to managerial insights and derive a policy for implementation.

- 1 The prediction of student's enrollment decision is hard.
- 2 The research is also limited by the availability of data provided by the institution under study.

The results from the optimization specify the scholarship awards to each applicant under a specific population and budget.

- The actual size and composition of the application pool could be affected by the unemployment rate and is random in nature.
- Uncertainty: Budget, SSI, etc.,. Use scenario analysis.

SSI dollars are distributed directly to Ohio's public colleges and universities through a formula primarily driven by enrollments that are classified into models based on levels of instruction and the statewide average costs of each model. For example, it costs more for a campus to offer an advanced engineering course than it costs to offer an introductory history course. Therefore, enrollments in introductory courses are funded at a lower rate than enrollments in more advanced courses.

Logistic regression generates the coefficients of a formula to predict a logit transformation of the probability of the binary outcome:

$$p(1 | x) = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \dots + \beta_k x_k \quad (1)$$

where p is the probability of the binary outcome of interests.

The logit transformation is defined as the logged odds:

$$Odds(p) = \frac{p}{1-p} = \frac{\text{Prob of yes}}{\text{Prob of no}} \quad (2)$$

And

$$\log_x odds(p) = \ln \frac{p}{1-p} \quad (3)$$
